Introduction

James L. Reuter
Associate Administrator
Space Technology Mission Directorate

The images of Jupiter are arresting. The updates from Mars riveting. We are daily learning new details about our changing climate, watching hurricanes form, and getting ready to peer deeper into our universe than ever before. All this groundbreaking work requires NASA's scientists and engineers to continually innovate and create advances in technology, techniques, and capabilities.

But all that innovation doesn't stop here at NASA. Thanks to the efforts of the Agency's Technology Transfer Program and the many companies, small and large, that partner with us, the same technology created to understand our planet and explore the universe are applied to challenges right here on Earth.

For more than four decades, NASA's *Spinoff* publication has documented more than 2,000 of these "spinoff" stories, from the NASA missions they originated with to their successful launches as commercial products and the benefits they've brought the public. In this iPad app, you can read about the latest success stories of commercialized NASA technology, along with videos and image galleries that let you explore the benefits of space in your life.

If you'd like to learn more about any of the technologies in this app, or if you'd like to request your own free print version of *Spinoff*, please visit us at http://spinoff.nasa.gov. To learn more about NASA's Technology Transfer Program, where spinoff technologies get their start, please visit http://technology.nasa.gov.

Health and Medicine

Keeping astronauts healthy often requires innovation that advances medicine on Earth, too—but that's not the only way NASA's work benefits human health. Whether collecting routine medical data or combating the microbes that make astronauts sick, NASA pushes the boundaries of what's possible in operating rooms and doctor's bags around the world. This section features stories used in trade books—books that highlight DNA damage, and a unique polymer that could help repair damaged heart tissue after a heart attack—all having their roots in a realm of expertise stemming from NASA missions.

Unique Polymer Finds Widespread Use in Heart Devices

A material that a NASA scientist stumbled on in the early 1990s has now helped keep hundreds of thousands of patients' hearts beating properly all over the world.

In the 1990s, working under the High-Speed Research Program, Langley Research Center scientist Bryant Wilkes was examining polymers for use as advanced composites for aircraft wings. He was looking for a substance with a unique set of qualities. This polymer—a class of highly durable materials that make great electrical insulators, among other properties—remained solvent when it shouldn't have and, under certain conditions, could be melted even after it was insoluble. It resulted in different useful forms at each of the three steps in the polymerization process. Today, that substance is a component in many different devices.

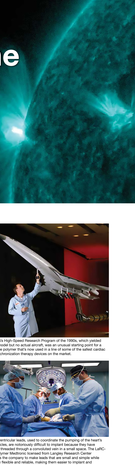

Bryant helped Langley patent the formula and process as Langley-St Jude Medical Center-Soluble Imide.

In 2004, Minneapolis-based Medtronic licensed LaRC-SI, and the company has incorporated Bryant on as a consultant, a role he still fills. They spent years developing a process for the material as a coating and electric insulator for the thinnest left ventricular leads available.

Traditional pacemakers address a slow heartbeat by delivering an electrical charge to the heart's right atrium and right ventricle. About 40 percent of patients with congestive heart failure or cardiomyopathy, however, have a delay between the right and left ventricles. This significantly reduces pumping efficiency and can be addressed by a regular pacemaker.

Cardiac resynchronization therapy addresses this problem by inserting a third lead to the left ventricle. It's a challenging procedure, because the lead has to be threaded through a vein that's often convoluted in a small space.

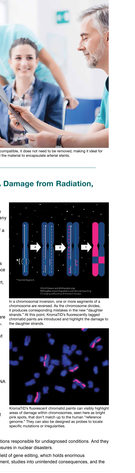

Using LaRC-SI as its insulator lets the lead be exceptionally thin and flexible while also sacrificing strength or reliability, making Medtronic's left ventricular leads, when it's the safest and easiest to implant on the market.

NASA's High-Speed Research Program of the 1990s, which yielded this material, is a long way behind. Like all of our planes, the Space Shuttle has been retired, but the polymer it helped perfect has saved cardiac resynchronization therapy devices on the market.

Left ventricular leads, used to coordinate the pumping of the heart's ventricles, are notoriously difficult to implant because they have to be threaded through a convoluted vein in a small space. The LaRC-SI coating Medtronic uses on its leads is thin and flexible, allows the company to make leads that are small and simple and highly flexible and reliable, making them easier to implant and maximizing patient safety. (top-contact.mcs.cmu)

Medtronic's left ventricular leads, the thinnest on the market thanks to a coating based on a NASA license, have helped to keep hundreds of thousands of people healthy and active.

Material for Mars Makes Life-Saving Sutures

For NASA, "the mission to return astronauts from Mars has been at the top of the planetary science to-do list for some time," says Andy Klesh, a University of the Jet Propulsion Laboratory (JPL).

"Rather than being concerned with the limitations of how much hardware we can deliver to Mars, we can apply all of the hardware, all of the knowledge on Earth, to a Mars sample return mission," he says.

But bringing back a sample requires putting it in a container with a strong seal, both to keep Earth's atmosphere from contaminating the sample, and to protect Earth from any potential contamination from Mars. "The trouble is, when you're getting

This diagram shows a lid specially designed for a Mars sample container. The lid has a layer of ePTFE (purple) on the top and the edge of the base that goes underneath it. The bioresorbable polymer (gray) is the material that would be pushed into and then around the inside of the lid that would block any cross-contamination.

To make a material tough enough to resist all of the dust but stiff enough that the metal base could cut through, Klesh and his team needed to innovate. The resulting material has been used in a variety of applications, including as sutures for procedures like heart surgery.

Extruded ePTFE is soft, flexible, and strong, and because it is biocompatible, it does not need to be removed, making it ideal for use in the human body. Among other applications, Zeus has used the material to encapsulate arterial stents.

Fluorescent Paints Spot DNA Damage from Radiation, Gene Editing

A new technique for detecting chromosome damage shows enough promise that space medicine that its creators founded a company to market it. They say that the new technology would push put them at the forefront of a revolution in genetics.

That same year, unbeknownst to the founders of KromaTID Inc., a team in France demonstrated that a feature of bacterial DNA called CRISPR, for clustered regularly interspaced short palindromic repeats, serves as an adaptive immune system. Researchers have since found that these snippets of DNA can be used to turn genes on and off and to edit DNA sequences in short, to edit genes.

But the potential for gene editing can't be realized until its side effects, such as unintended damage, are understood.

NASA has studied DNA damage because astronauts are exposed to charged particles that can be found in the ionizing radiation harm. For years, doctors at Johnson Space Center took blood samples from every astronaut before and after trips into space, checking for genetic damage.

Although they could detect the translocation of DNA—when a bit of one chromosome ends up fused to another—they couldn't see subtler forms of damage. KromaTID's technique promised the ability to spot inversions within a chromosome, where a stretch of DNA gets flipped backwards.

In 2008, Johnson awarded two Small Business Innovation Research contracts to the Fort Collins, Colorado-based company. It was KromaTID's first funding, and it helped prove and refine the technique it calls directional Genomic Hybridization.

KromaTID's DNA probes can help doctors select and tailor cancer treatments and help researchers identify patients for clinical trials. They've found the DNA variations responsible for undiagnosed conditions. And they can help geneticists determine suitable targets and exclusions in nuclear disasters.

But the company sees its biggest opportunities in the field of gene editing, which holds enormous possibilities for health and industry but requires refinement, studies into unintended consequences, and the establishment of standards and guidelines.

In a chromosomal inversion, one or more segments of a chromosome breaks off, flips around, and reattaches. Because it produces corresponding mistakes in the new, lengthier DNA sequence, inversions can be difficult to detect. Fluorescent chromatid paints are introduced and highlight the damage to the daughter strands.

KromaTID's fluorescent chromatid paints can visibly highlight inversions and other chromosomal damage. Its technique is the only one, quite quite, that don't match up to the human "reference genome." They can also be designed as probes to locate specific mutations or irregularities.

NASA uses Kromatid's technology to oversee DNA from astronaut Scott Kelly, left, and his identical twin Mark Kelly and after Scott Kelly's record-breaking stint in space. As expected, the astronaut's DNA showed some damage after his return, while his twin's was unchanged. The damage, however, was minimal.

Image-Analysis Software Sees Cancer in 3D

Even NASA can be surprised. The Space Agency wants to search out surprising discoveries, of course, but it also wants to avoid any surprises when it comes to the safety of its astronauts.

But even with decades of study on health risks, notes Craig Kundrot, division director for NASA's Space Life and Physical Sciences Research and Applications, there are still unknowns. For example, "when we went from two-week Shuttle missions to six-month space station missions … all of a sudden we started seeing these vision problems," he recalls. "That caught us by surprise."

Although NASA is still working to fully understand the details of these vision changes and what causes them, researchers believe they are related to blood flow changes in microgravity, which is something that has been studied extensively.

In one 2011 study on vascular changes in microgravity, funded by Ames Research Center, Mulugeta Gebrib and his colleagues set out to test the hypothesis that these changes impact heart and bone loss. Part of his study included analyzing images of tissue samples from the hind legs of mice that had flown on the Shuttle, to count the blood vessels and measure their thickness and shape.

NASA-licensed Amira® software has been used for more than a decade by the ground-based Subaru Telescope in Hawaii that will help shed new light on the 95 percent of the universe that is made up of dark matter, a fact few astrophysicists realized the expansion of the universe by mapping the red shift of distant galaxies.

The problem is, interpreting the data can be difficult, as is measuring the vessels. "Any manual accounting, even by highly trained technicians, would have been subjective," Mdura notes.

Instead, Mdura decided to turn to computer analysis software made by Image IQ, now owned by Philadelphia-based FEI. The company custom-developed an algorithm that segmented each image into five different regions and then used further analysis to detect two different stains within each region. It also created a filter that helped the computer better differentiate between the stained blood vessel and the surrounding tissue.

The software has since been used for many clinical studies. One potentially life-saving example: using the fibers and algorithms created for Mdura, researchers can identify the three-dimensional shape of a tumor, which can give better insight into whether it is growing and whether it is metastatic or benign.

Using fibers and algorithms created for Ravi Mdura's NASA-funded vascular study, researchers today are able to identify the three-dimensional shape of a tumor within an image series. Among other features, the software is excellent at finding edges in a way that might not even be visible to the human eye.

Miniature Positioner Focuses Lenses with Precision

Nobody has ever directly seen dark matter or dark energy, yet physicists and astronomers observe their effects all around us. Researchers are working to better understand these mysterious phenomena—and NASA is helping design the next generation of powerful instruments that will hopefully lead to big discoveries.

One instrument that could offer important new clues, built with the help of engineers from the California Institute of Technology and the Jet Propulsion Laboratory (JPL), is due to be installed on Japan's Subaru Telescope in Hawaii in 2019.

The tool, called a fiber-fed spectrograph, measures the composition of light from objects in space. It will collect galaxies' spectra of more than 2,000 fibers at a time, with a spot on the image to analyze its color spectrum.

That requires thousands of miniature positioners, powered with tiny piezoelectric motors, to move each fiber into the right spot, JPL worked with Victor, New York-based New Scale Technologies to perfect the rotary motors. Importantly, the company reduced the required power to less than 10 volts and improved its precision manufacturing to ensure each product was identical.

Today, "everything we do now is at 10 volts or below," emphasizes New Scale CEO David Henderson. "Even some of our more powerful products are now using reduced-voltage drives. It's essential for our mini-mechatronic solutions."

The company has also expanded its product line, from single-axis positioners to those with two, three, or rotary modules, as well as offering multiple motors with a positioner.

New Scale's products are showing up in a variety of contexts, including medical instruments. One, a portable blood analyzer, uses a positioner with a rotary stage for an embedded microscope. The analyzer fits in a backpack and can field-test someone for HIV. The company is also getting interest for implantable devices to use in robotic surgery.

Dark matter can't be seen, but scientists observe its effects on galaxies. To help researchers understand it and gas within surrounding galaxy clusters, and the inferred position of Dark Matter (blue) through the effect of gravitational lensing.

Each of nearly 2,400 fibers on the fiber-fed spectrograph will receive independent positioners and tracking of light that can cover any point on the image. New Scale Technologies developed the miniature motors that power the positioners, a precision that could help monitor HIV. The company now uses the technology on many of its products, including the one that fits in a backpack and transmits, like a portable blood analyzer that tests for HIV.

Biometric Sensor Tracks Vital Signs for Health

Many people already keep track of their heart rate, whether with a smart watch or an exercise monitor. But for a 2012-2014 project funded by NASA, researcher Lino Velo was interested in going deeper.

The purpose of the program was to be able to detect whether a subject, in this case an astronaut, is under stress," he explains, and the goal was to create a wearable device that detected this stress in real time.

In particular, Velo was interested in cognitive load. "If you have to think fast and reason and be very alert, that kind of stress is what he focused on," he says.

Funded by Small Business Innovation Research (SBIR) contracts from Johnson Space Center, Velo invented the EPD, a biometric monitoring sensor that tracks heart rate variability, a measure of the spaces between beats that can indicate stress level.

Sabulon sells a smart watch, the Zoom HRV, that measures heart rate variability using a blood flow sensor developed with Fondo Nacional de Ciencia, Johnson Space Center. The watch also monitors sleep using additional sensors developed under separate SBIR contracts.

Now Newark, California-based Sabulon sells the sensor to wearable-makers and directly to consumers. One model that incorporates the PPG sensor, available from Sabulon's website, is the Zoom HRV. It also incorporates actigraphy—monitoring rest-activity cycles—and sleep sensors (the latter were developed under separate SBIR contracts with NASA).

For now, Velo says, the core audience appears to be people interested in tracking fitness—the heart rate variability data is helpful for athletes who want to know if the body is recovering during rest periods.

But he sees potential for these devices to help monitor health more broadly. By monitoring heart rate variability over weeks and months, for example, users can immediately be alerted to a change from the baseline, which suggests the body is becoming stressed.

"We're trying to address this from an individual before he or she gets into any kind of ailment—trying to be ahead of the curve to help people," he says.

Transportation

Not many humans ride in rocket ships, but all of us have benefitted from the technology created to get the lucky few into orbit and beyond. We see space innovations in everything from sensors created for the Apollo program that are now finding their first commercial innovations that could power all electric aircraft. Also in this section is software that helps spy planners and lawmakers—and new developments in aerospace technology that could soon serve as a lighter-weight substitute for plastic in cars and planes.

Battery Innovations Power All-Electric Aircraft

As NASA develops its X-57 Maxwell aircraft, the agency is tackling the challenges of building all-electric aircraft and passing the solutions on to private industry. One difficulty it overcame with help from industry was creating a battery pack that can withstand the plane's motors, weighs as little as possible, and meets stringent safety guidelines.

The X-planes, experimental aircraft built by NASA and the military, started out by breaking the sound barrier and have been pushing through invisible barriers ever since. The latest, known as the X-57 Maxwell, aims to make all-electric passenger aircraft a commercially viable reality.

The plane is a highly modified Tecnam P2006T, a four-person, twin-engine craft. Engineers at Armstrong Flight Research Center are replacing its gas-powered engines with two electric ones, and they're changing the wings, reducing drag from wingtip vortices. Six smaller motors along the leading edge of each wing add to the airflow, increasing lift during takeoff and landing.

One big challenge a battery allowing enough power to the motors. Engineers called on Electric Power Systems (EP Systems), based in Industry, California, to develop a battery pack, funding the effort with Small Business Innovation Research contracts.

The 850-pound pack holds thousands of lithium-ion cells, each in a cylinder about the size of an AA battery. The downside to lithium-ion cells is that they can short-circuit and start a "thermal runaway," ending in combustion, so the pack had to contain the fire. Cells can't just bump into flames, it wouldn't set off a chain reaction—which is exactly what happened during month. EP Systems says the batteries it's providing for the X-57 contain some improvements.

EP Systems says it has received considerable interest—and yet unannounced contracts—from companies looking to build all-electric aircraft for short flights between small airports and vertical-takeoff and -landing vehicles for transportation within cities.

Without the assist from Armstrong, says Nathan Millecam, president and CEO of EP Systems, electric propulsion batteries might not have gotten off the ground. "If NASA didn't have the foresight to see aviation going this way and the problems that need to be solved to get it there, this never would have happened."

With NASA's help, Electric Power Systems (EP Systems) created this battery pack to power the space agency's all-electric X-57 Maxwell aircraft. The pack contains thousands of cells, which are similar to batteries and ensures that if one of them overheats, the problem won't spread.

Bye Aerospace's Sun Flyer, an all-electric training airplane that's already flying, has a battery pack similar to the one NASA is using for its Maxwell aircraft on the one it built, with NASA funding and expertise, for the X-57 aircraft.

Shuttle Tire Sensors Warn Drivers of Flat Tires

Proper tire pressure is crucial for a safe landing, but in the early days of the Space Shuttle Program, there was no good way to accurately gauge pressure in flight. Instead, engineers relied on extensive pre-flight ground tests to measure air loss over time.

How many people have been surprised to realize their car tire was dangerously low on air? It was something the Space Shuttle engineers worried about too.

The Shuttle had four rear tires, two under each wing, and if even one was low on air during landing, it would be a "very bad day," says Steve Sostaric, a Kennedy Space Center flight engineer.

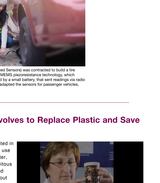

Originally, an externally mounted strain gauge monitored tire pressure in flight, he says, but it only gave a very rough estimate of pressure. Instead, Shuttle engineers relied on extensive pre-flight ground testing to learn the rate at which the tires lost air, so they could determine if there was enough margin for a safe during landing.

Looking for something better, in the 1990s, Kennedy partnered with a then-start-up called NovaSensor to build a tire pressure sensor on a silicon chip, powered by a small battery, that alerted pilots if the pressure was low.

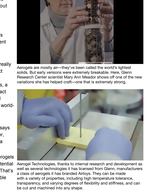

The company, now part of the Minnesota-Pennsylvania-based Amphenol Advanced Sensors, soon started work on the car tire sales and many millions, most of which ended up on U.S. passenger vehicles, including those by Ford and GM.

Today, U.S. law mandates a pressure gauge on every car tire, and that's because of the increased safety pressure sensors like these enable. Even when the pressure isn't low enough to cause a blowout, adds Amphenol's Mark Readey, low tire pressure makes the car run less efficiently, using more fuel and wearing through the tires faster.

Amphenol continues to sell the NovaSensor P1602, which, despite upgrades, is essentially the same product created 25 years ago. Though no longer a major part of Amphenol's business, Readey says, the tire pressure sensors "definitely played a critical role in first making us profitable—it helped us turn the corner in terms of becoming a real company."

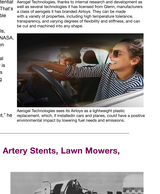

Astronaut and pilot Michael Bloomfield tests the heat resistance of a tire that will be used on the space shuttle in 1991 flight. The friction from the runway used to wear the treads off the tires, leaving a narrow margin between the tire's steel belts and disaster. One of the challenges was to improve the tire durability as well as add sensors to constantly monitor tire pressure.

NovaSensors, (since acquired by Amphenol Advanced Sensors) was contracted to build a tire pressure sensor for the Shuttle. The company used MEMS (microelectromechanical systems) that converts pressure into electrical resistance, powered by a small battery, that sent readings via radio frequency to the cockpit. The Shuttle sensors adapted the sensors for passenger vehicles, ultimately selling many millions of the device.

Space-Age Insulator Evolves to Replace Plastic and Save Weight

Aerogels are mostly air—they've been called the world's lightest solids. But early versions were extremely breakable. Here, Glenn Research Center scientist Mary Ann Meador shows off one of the new iterations she has helped craft—one that is extremely strong.

When aerogels were first invented in the 1930s, nobody had much use for them. Nearly a century later, these materials could become as ubiquitous as plastics, says one entrepreneur—and it never would have been possible without NASA.

Aerogels are made by creating a gel and then carefully removing all the liquid. The delicate structure that remains is the world's lightest solid—in some cases over 99 percent air, contained within nanopores distributed throughout a thin network of solids.

The commercial potential of aerogels only really got a jumpstart after NASA and its project figured out how to turn the famously brittle material into something useful. In the 1990s, a Small Business Innovation Research contract funded the development of aerogel space blankets, which were durable, flexible, and world-class insulators.

Since then, NASA has continued funding research into the materials. Most recently, says Glenn Research Center's Mary Ann Meador, "we've been working on using aerogels as a substrate for antennas."

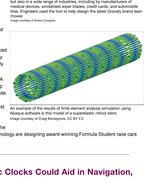

But Meador is among the first to say the aerogels she has helped create have many other potential applications, including well outside NASA. That's why Glenn made its aerogel patents available through the Technology Transfer Program.

The compelling properties of these materials, plus the low cost of licensing patents from NASA, says Aerogel Technologies founder Stephen Steiner, make licensing Meador's patents "a no-brainer." Now, after additional in-house R&D, the Boston-based company is selling the material, which it has branded as "Aerius," to a variety of industries, from airplane and car manufacturers.

"Because they have plastic-like properties, our products are able to go into cars and airplanes to make them lighter—and that make them tremendously more fuel efficient," he emphasizes.

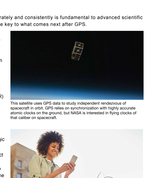

Aerogel Technologies, thanks to internal research and development as well as several technologies it has licensed from Glenn, manufactures a class of aerogels it has branded Aerius. They can be made flexible, as shown here, and also have other properties—including transparency, and varying degrees of flexibility and stiffness, and can be cut and machined into any shape.

Aerogel Technologies sees its Aerius as a lightweight plastic replacement for many applications, which can also have a positive environmental impact by lowering fuel needs and emissions.

Software Helps Design Artery Stents, Lawn Mowers, Airplanes

A photograph taken of Aloha Airlines Flight 243 in April 1988 after it made an emergency landing. Unexpected fatigue cracks led to the structural failure of the top half of the fuselage, exploding crew and passengers to the sky. Engineers at Langley Research Center developed software known as Structural Analysis of General Shells to help determine the cause of the incident.

Photo courtesy of the National Transportation Safety Board

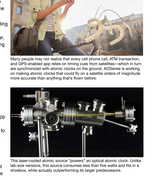

When Aloha Airlines Flight 243 made an emergency landing on Maui in April 1988, much of its upper fuselage was missing, leaving passengers entirely exposed to the elements. Remarkably, only one person died. Because the Boeing 737 was designed to resist exactly this type of cracking, and it was unclear how the damage occurred.

Researchers at Langley Research Center tasked with supporting the aeronautics industry created models of the fuselage using the Structural Analysis of General Shells (STAGS) software. Marc Horner was developing under a contract from the center. STAGS was one of several improvements being made at the time to finite element analysis (FEA) software, which breaks a structure down into tiny elements to engage it and simulate its behavior.

One such software suite is Abaqus FEA. When French software company Dassault Systèmes bought Johnston, Rhode Island-based Abaqus Inc. in 2005, the programming needed to be updated to account for new composite materials and manufacturing processes. Its developers created a Fracture Customer Review Team that included NASA engineers, with whom it met regularly for the next decade.

Among other improvements, developers added many capabilities of the STAGS code. As the company issued updates, NASA engineers often helped test them and ensure they met the Agency's needs. The relationship continues to this day. Abaqus developers are now part of NASA's Advanced Composite Project, a consortium of industry and other partners who participate in weekly teleconferences.

Today, a host of industries use Abaqus FEA software. Engineers have used it to develop windshield wiper blades, tires, and composite airframes. It has helped model dental and human hearts. Engineers used it in the latest Gravely brand lawn mower, which has 50 percent fewer parts and lower production costs than predecessors. And students on the Norwegian University of Science and Technology are designing award-winning Formula Student race cars with the software.

An example of the results of finite element analysis simulation using Abaqus software is this model of a supersonic retard stent.

Super-Accurate Atomic Clocks Could Aid in Navigation, Communication

The best atomic clocks currently made "won't lose a second in the entire life of the observable universe," says Goddard Space Flight Center's Gregory Heckler. Unfortunately, those clocks tend to fill up an entire laboratory.

One company working on making them portable is Sunnyvale, California-based ADVenture Inc., with the help of several Small Business Innovation Research (SBIR) contracts from NASA, among others.

"We're doing the engineering necessary to make [optical atomic clocks] a lot smaller, a lot more robust, and able to operate autonomously and at low power," says ADVenture's former vice president of strategic planning, Jamil Abo.

ADVenture has already completed a compact laser-cooled atom source that operates on less than five watts and is "small enough to fit in a shoebox"—all while outperforming the large academic versions.

That means "the academic labs aren't building their own anymore—they are buying ours," Abo says. Sales are just in the tens per year, he says, "but it helps sustain our ongoing efforts."

The company has also used NASA SBIR contracts to develop the clock laser with sales on the order of a few years and the frequency comb.

They anticipate a larger market for the completed clock—and a wider impact. Already, people rely on satellite synchronization for every cell phone call, every ATM transaction, and every phone app that uses GPS. "Ultimately, if you want to know your position to 10 meters, you need to know your time to roughly 10 billionths of a second," Abo explains.

Right now, the GPS satellites that provide this timing reference synchronize with atomic clocks at the Naval Observatory, but ADVenture sees a future where each satellite could have its own. Likewise, an inertial navigation system built into the vehicle, using an atomic clock, would be safer than relying on jammable and hackable GPS.

This satellite uses GPS data to study independent rendezvous of spacecraft in orbit. GPS relies on synchronization with highly accurate atomic clocks. ADVenture, Inc. but NASA is interested in fixing clocks of that caliber on spacecraft.

Many people may not realize that every cell phone call, ATM transaction, and GPS-enabled app relies on timing cues from satellites—which in turn are synchronized with atomic clocks on the ground. ADVenture is working on making those clocks smaller, lighter, and hundreds of orders of magnitude more accurate than anything that's flown before.

Probes Characterize Air and Water Flows over Aircraft, Yachts

A new approach to analyzing high-speed turbulence in wind and fluid flows is on track to become the new standard for such kind tunnel measurements—and is finally catching on in the aircraft-design industry and even among yacht builders.

Anemometers are devices that measure air speed, and Tao Systems Inc., based in Hampton, Virginia, first pioneered the constant voltage anemometer (CVA) under two Small Business Innovation Research contracts with Langley Research Center in 1995.

Langley Research Center's Unitary Plan Wind Tunnel. Tao Systems' CVAs measure liquid velocities just as well as they measure wind speeds, and they've been used to design America's Cup-winning yachts. Langley's newest wind tunnel, the National Transonic Facility, is the high-bandwidth, multichannel Model 4 600 (inset) is currently under testing at Langley to compare the CVA with other types of anemometers.
Image courtesy of Dave Ferry, CC BY 2.0

The CVA, as well as constant temperature and constant current anemometers, usually use probes consisting of a tiny wire with an electrical charge that heats it. The faster air or other fluid passes over the wire, the faster it draws heat from the wire. Because the wire's resistance decreases at lower temperatures, the anemometer can derive the velocity from the resistance in the wire. Unlike its cousins, the CVA holds input voltage constant, deriving flow velocity from output voltage.

Capable of up to 30 measurements per second, the CVA is especially advantageous for high-speed wind tunnel testing. Measuring small aerodynamic structures at high speed requires extremely high frequencies. The probes can also detect temperature fluctuations, becoming sensitive to temperature only at low voltage levels that lead to heat the sensor.

Because it can rapidly shift back and forth between low voltages that detect temperature and higher voltages that sense velocity, the CVA yields much faster results than other anemometers. Conventional systems use software that senses at different dedicated temperatures and risk burning out if temperatures change too rapidly. The CVA also produces a cleaner, less noisy signal.

Langley is currently testing the CVA against other anemometers in wind tunnel testing.

While the primary users for the technology will likely continue to be NASA, the military, and aircraft manufacturers, the CVA has other applications, such as monitoring heat flows in fuel cells and characterizing the fluid dynamics of yacht sails. It's even been used to design America's Cup-winning yachts.

Public Safety

Safety and security are among the most basic and fundamental societal needs and values. Advanced technology is vital to our nation's ability to create safe and secure environments for our citizens and to maintain our economic vitality. The U.S. government is responsible for ensuring that the nation's critical infrastructure remains secure and resilient. This includes cyber and physical infrastructure that enhances essential services such as communications, power generation, water and food supply, transportation, and emergency services. Actions taken by the government must protect the nation's way of life in the economic, security, and social spheres.

NASA Brings Accuracy to World's Global Positioning Systems

The Jet Propulsion Laboratory's (JPL) Global Differential GPS (GDGPS) System is a system to determine the precise locations of a network of radio telescopes was what initially led to the creation of the most accurate and location-based navigation GPS.

In the 1980s, as the U.S. Air Force was launching GPS satellites, JPL started building its GPS tracking network, calculating the first ground stations with centimeter accuracy.

But GPS data was not sufficiently accurate enough for errors and delays. GDGPS GAGAN, the software that JPL developed, is a system that corrects GPS errors and provides a much more widely licensed software programs. When the internet became widespread in the 1990s, JPL developed Real-Time GPS (RTGY) software to make these corrections in real time via the internet.

An early investor was the Federal Aviation Administration, which made RTG the prototype for the Wide Area Augmentation System, a safety-of-life navigation system that allows for navigation and guided landings.

An economic spinoff of that came to be called Global Differential GPS (GDGPS). In 2002, the Air Force Research Laboratory asked JPL to develop a system of information about satellites and upgrade its GPS operations, which JPL and other GPS engineers.

One early adopter of GDGPS was Long Island Railroad, which wanted to use GPS to automatically control its trains. Another early GPS customer was Deere & Co., which began using GDGPS to guide its farm equipment. Other GDGPS customers of others around the world as well as other companies' use of GDGPS is also the reason why GDGPS is used in autonomous vehicle navigation systems, in measuring the movement of dams and in the fast search-and-rescue beacons in aircraft and spacecraft.

The GDGPS enabled the first self-driving farm tractor, which was developed by Deere and Carnegie Robotics. It is also commonly used in surveillance of drilling, mapping, surveying, construction, and Earth's crustal motion. Environmental scientists have also used to detect earthquakes and warn of tsunamis. And GDGPS now supports the world's other navigation satellite systems.

While NASA has always been a key user of GDGPS technology, private companies have become the primary customers for many other government and commercial users.

The Jet Propulsion Laboratory's (JPL) giant crosshairs with the Global Differential GPS (GDGPS) System, a system to determine the precise locations of a network of radio telescopes that was what initially led to the creation of the most accurate and location-based navigation GPS. The system corrects GPS errors and provides a much more widely licensed software programs. When the internet became widespread in the 1990s, JPL developed Real-Time GPS (RTGY) software to make these corrections in real time via the internet.

The Federal Aviation Administration invested in Global Differential GPS (GDGPS) to make its Wide Area Augmentation System (WAAS) a navigation system, which was also the site of thousands of GPS ground stations around the world, which JPL used to develop an orbiting, using GPS guidance.

The first major commercial customer for GDGPS was John Deere, which worked closely with JPL scientists to make the system accurate enough to guide its farm equipment. Other commercial users of GDGPS have since offered precision agriculture commissioned around the world.

Deere & Co. began using GDGPS to guide its farm equipment. Other GDGPS customers of others around the world as well as other companies' use of GDGPS is also the reason why GDGPS is used in autonomous vehicle navigation systems, in measuring the movement of dams and in the fast search-and-rescue beacons in aircraft and spacecraft.

Through NASA's GPS Real-Time Earthquakes and Tsunamis (RTGY) program, GDGPS is used to predict and warn of impending tsunamis all over the world, and also to monitor earthquakes.

Gas Regulators Keep Pilots Breathing

In 1982, John Clarion became the first American to reach orbit—and he was able to breathe thanks to a pressure regulator made by Airgas Corp. The gas controls maintain a steady level and distribution of the same technology—and commercial airlines pilots rely on. Airgas's regulators are used in the cockpit oxygen masks of commercial airliners.

It worked with a gas engine that no longer exists.

That's why engineers had problems with Nemecks," explains Jim Tally, vice president of engineering at Airgas's Aerospace Systems unit. "We've been in this field based business unit of Clarion PLC. The solution required injecting oxygen to maintain the engine, but it was the optimized control and flow of oxygen to the engine.

The solution Clarion built is a small mechanical regulator that uses a diaphragm to control the pressure of oxygen that passes through to relax the flow of the spring. Previous versions were too big to fit in the cockpit, but Airgas's new regulator is about the size of a softball.

Clarion (then operating as Carleton Controls) innovated by combining two different types of regulators in a new way, which maintained performance even if the flow of oxygen was interrupted. It was to best choose between oxygen or breathing air.

Finally, the company still uses the spring-arrangement and its oxygen-sufficiency ratio in its latest products, including breathing regulators used in emergency oxygen systems for pilots of most major airlines.

Airgas's Aerospace Systems unit has a handful of our equipment. That gives our customers in the military and commercial aviation the confidence that we know what we're doing," says Tally.

Other applications include military planes and submarines, as well as for the breathing parachutists jumping from high altitudes. Airgas is also developing a new regulator for use to back clean breathing air supply oxygen—between 50 and 90 per cent.

Airgas's Aerospace Systems unit has a handful of including wastewater treatment and offshore drilling.

Airgas's Aerospace Systems unit has a handful of our equipment. That gives our customers in the military and commercial aviation the confidence that we know what we're doing," says Tally.

Tally's new commercial airlines equipment with emergency oxygen systems to make the technology Carleton Masters Aerospace Systems unit has a handful of our equipment. That gives our customers in the breathing system whenever the plane like an affordable airplane oxygen.

Carleton's gas regulators, which maintain a small and lightweight to work in space, are now also used by high-altitude parachutists.

RoboMantis Offers to Take Over Dangerous Missions

At the 2010 DARPA Robotics Challenge, working with Boston Dynamics, Carnegie Mellon University's (CMU's) RoboSimian drove a vehicle, cleaned a path through rubble, cut a hole in drywall, and climbed a set of stairs—all tasks that DARPA had set for CMU's entry. Its name, like body on four limbs. Actually, the simian, the autonomous automation navigated its surroundings with sensor and of dual cable cameras and a lidar unit. The device processing my joints include brakes and motors. Each limb has a "hand" that can be outfitted to a matter it "gloves" to accomplish different tasks. The system assumes that speed comes not from rapidity but from the ability to work continuously.

RoboSimian represents the CMU's in the competition. Even before the finals, the California Institute of Technology which manages JPL, had the idea to develop a robot for dangerous jobs, a similar toolbox of robot technology. Its RoboMantis, like RoboSimian, is designed in California, uses based the technology, using it as a starting point for a next-generation version. That robot, the Lemur, was developed by Caltech researchers, who unveiled in January of 2014.

For the 2.0 version, the company created new software, modular interfaces, and controls, as well as a new power system. While RoboSimian is so stable that its creators don't bother to strap it down, RoboMantis is designed to be more nimble, with the ability to keep four limbs on the ground while working.

The company markets the robot in any company or industry that requires a robot to perform dangerous tasks. It shouldn't refer to it at and gets industry—where it can

The RoboMantis is based on a robot developed by Caltech researchers, who unveiled in January of 2014. Consumer Goods

What's new, what's next and what's beyond. Our writers cover the latest in consumer technology, from smartphones to smart homes. Also, a look at the companies behind the products and services we all use, and through out the household gadgets that will change the way we live.

Bowflex System Spurs Revolution in Home Fitness

The commercials were once ubiquitous, and the machine occupied storefronts in spare rooms and garages across America. Bowflex, the poster child for a phenomenon of the 2000s—an exercise system that promised to bring the total gym experience into the home—and it continues to sell well today. But it might not exist if not for Nautilus.

In the 1980s, mother Paul Fanous had an idea for a weight-lifting system that didn't use free weights. Instead, it used resistance bands to provide resistance. Nautilus's dominant technology at the time was compact strength-training equipment that used steel weight stacks. At the time, NASA was struggling to combat the effects of weightlessness on astronauts during after prolonged periods in space. Weightlessness is treadmills and stationary bikes weren't enough. Fanous's company, Nautilus Sports/Medical Industries, quickly learned of this. He contacted Johnson Space Center. After demonstrating the prototype of the SpaceFlex, Johnson asked the team to modify Cushman's flesh-to-air attachment system.

A year and a half of development and testing resulted in the Interim Resistive Exercise Device, which astronauts used on the Space Shuttle Columbia in 1991. Fanous's device was a fully developed, flight-ready and validated mechanical system.

In the early 2000s, when Nautilus Inc., based in Vancouver, Washington, was looking for an alternative to its old-based flywheel technology, Fanous presented the company with a new idea: a home exercise machine based on the system he worked on helping the company design the Resistance based on SpaceFlex. It launched in 2005 to become Nautilus' most successful line.

"The biggest advantage of resistance-based workout machines is that they're safer," Fanous says. Instead, take a new look, and he says, "I'm not a big fitness fanatic" as he is about how management at the company.

While the Resolution only weighs about 220 pounds, its big cross station can provide up to 600 pounds of resistance. Fanous says that's enough to challenge even the most weight-trained athlete. Resolution also eliminates the momentum free weights generate during lifting, which can be hard on joints and allow the user to create a lot on the opening.

The SpaceFlex FlexTrainer, originally developed for NASA, was adapted at Nautilus to adjust the Bowflex Revolution's resistance.

Astronaut Sandra Williams poses while using the Interim Resistive Exercise Device on the ISS. The cylinders at the base of each side provide the resistance. Nautilus's Bowflex Revolution uses a similar, but smaller, mechanism. They sucked up air to power the Bowflex Revolution, which was developed for NASA.

A crowd views astronauts on the Space Station, wearing an early prototype of the Bowflex Revolution. The device was used by astronauts aboard the International Space Station in the Pleiades crew of the station.

Spacesuit Air Filters Eliminate Household Pet Odors

In a surprising turn, NASA-backed research into new spacesuit technology could improve air quality in the homes of millions of pet owners. A team of engineering friends and their commercialization facilities.

After creating an air and water purification system for NASA's Constellation space suit, Jeff Wadhwa Energy unlimited Solutions Inc. in 2011, setting up an purification. The company's first product was the Sweetie, and most

Johnson Space Center awarded Siemens Corporation a Small Business Innovation Research (SBIR) contract in 2010 to fund a system for removing carbon dioxide from astronauts' exhaled and perspiration exhausted. Further Siemens SBIR contracts focused not just on spacesuits but also spacecraft air quality.

Siemens's CoroAir technology also changes the way the air moves through the suit, which can have a fan system, which can have unnecessary filter changes.

In the consumer market, ammonia happens to be an issue with pet owners. Ammonium is a natural component of animal urine and is in toilenses and experience the results of that research like never before, in an

Wadhwa's team developed the Multi-Filtration System, which uses a combination of activated carbon and zeolite to trap ammonia. Zeolite is a naturally occurring mineral that has a honeycomb structure that can trap molecules of a certain size. Wadhwa's team developed a zeolite that traps ammonia but allows water vapor and oxygen to pass through.

Siemens's SBIR-enhanced spacesuit, Siemens CoroAir filters changed more frequently than the Multi-Filtration System, requiring astronauts to swap out the filters.

Wadhwa's Multi-Filtration System filters ammonia from the air in a pet's environment. The filter is made of activated carbon and zeolite, a naturally occurring mineral that has a honeycomb structure that can trap molecules of a certain size. Wadhwa's team developed a zeolite that traps ammonia but allows water vapor and oxygen to pass through.

NASA Research Sends Video Game Players on a Journey to Mars

What would it be like to build a shelter on Mars? To plant a garden or explore its lava tubes?

NASA has spent years imagining—and planning for—the Red Planet's exploration, and it's been a key source of inspiration for video game designers. Now, a new game from NASA's Jet Propulsion Laboratory aims to let players experience the challenges of living and working on Mars for themselves.

The free-to-play game, called Mars Base Delta, is a first-person adventure that combines survival elements with puzzle solving. Players will be tasked with building habitats, growing food, maintaining life support systems and conducting research—all while exploring the Martian landscape.

Mars Base Delta is the latest in a series of games developed by JPL that NASA hopes will make it to Mars," says Reyes. "And hopefully some of them decide to become scientists themselves and try to elaborate on these concepts."

Mars Base Delta, which is available for free, will initially contain the first of six episodes. Each episode will take players about two hours. Expert simulation of the material research was even used for many other features in the game, including the Space Buddies.

Mars Base Delta, which is available for free, will initially contain the first of six episodes. Each episode will take players about two hours. Expert simulation of the material research was even used for many other features in the game, including the Space Buddies.

Memory Foam Supports and Shapes in Women's Apparel

If there's one NASA spinoff almost guaranteed to have touched your life, it is memory foam. The spongy, pressure-sensitive material was a team of scientists at the material shows up in more and more consumer products, from mattresses to car seats and even to shoes.

But hit the famously cushy foam was invented for a NASA project to improve airline seating safety. "We decided to design a seats that would absorb the energy of impact," Ames Research Center engineer Alan Gelb managed the project.

One of the most important innovations, Kolcraft Enterprises, Inc., is the foam's "slow recovery" property. It takes a few seconds for the foam to return to its original shape, something the team tested extensively in the form of a car seat.

In the car.

It's couldn't find anything to fit the bill, so built one himself. And, after returning from China, he teamed up with fellow World founder and CEO Ray Wu to develop it into a product that was ready to sell.

The result is the Shower Head Water Purifier, a showerhead that connects to a faucet and filters out harmful impurities. The device is the first showerhead to be certified by NSF International, a public health and safety organization. Its design is also environmentally friendly: It's the first showerhead to be made entirely without lead, and its replaceable filters and a silicone rubber designed to clamp the air purifier to a shower hose.

Today, memory foam is one of NASA's most widely used spinoffs. The material is used in everything from mattresses to footwear to prosthetics to protective gear, and it's even been used to help astronauts sleep in space. Gelb, a veteran of NASA's aeronautics research, used memory foam in his own bed for a time that made comfortable to the body. Some others found it a bit too soft.

Rocket Design Leads to Turbo-Charged Air Purifier

The founders of Rural Water purposely have space exploration in their blood. Ray Wu is a rocket scientist at Lockheed Martin, and Chris Chinai is a mechanical engineer who has worked at Marshall Space Flight Center proved crucial when designing the first prototype. The idea was sparked when Jason Tin-Chi Chen, a Taiwanese businessman living in rural family and worried about the effects of air pollution. Most air purifiers are designed for urban areas, Chen found, and they don't work well enough to use in a cattle shed or in the car.

The company also makes a removable sensor that monitors air quality in a room and sends information to a smartphone app. Users can check conditions where they want to go.

Brainwaves Reveal Student Engagement, Operate Household Objects

When we talk about operating "on autopilot," we usually mean not doing with little thought or attention. Researchers now think that actual autopilots can cause actual pilots to behave in this way.

Ames Research Center, which tests how even more and more operations in the cockpit, pilots could grow bored, complacent and even disengaged—and therefore prone to "inadvertent slips of awareness," in the words of Ames human factors researcher Key Dismukes. Ames was looking for ways to identify and counter a pilot's cognitive state using brainwave monitoring.

The result was an engagement index" that's still used today, take-away output, which indicates how much attention a person is paying to what they're aware, which comes with measured attention as a measure of engagement.

The team found that subjects who were allowed to monitor their engagement levels were able to control the index—that is, to pay more or less attention on command. They also found that learning the exercises levels improved performance, even in the long term.

Now, the company is developing products for students founded Brainful Inc. in Berkeley, California, to help students learn how to control engagement to monitor students' attention and, ultimately, to help people with attention deficit hyperactivity disorder (ADHD) improve their ability to control their attention.

Brainful's Focus EEG headband monitors the wearer's brainwaves to determine attention level. The device is a modified version of the Muse headband, which was developed for meditation and relaxation. Brainful's version is designed to train the wearer to concentrate on a task and not allow the mind to wander.

Energy and Environment

Many of the technologies that will power the next generation of energy and environmental solutions are being developed right now in NASA laboratories and are already creating economic opportunities for companies ready to capitalize on them. Here are just a few examples of how NASA technology is helping to power the future.

Electrified Bacteria Clean Wastewater, Generate Power

NASA recently sent into space organisms that might sound like they came from space by-way of sci-fi—microbes that can essentially "eat electricity."

The Shewanella oneidensis bacteria traveled to the space station last February and use a metal outside the cell, instead of oxygen, as the final electron accepting step in their respiration process. As a result of both of similar microbes, known as "electrigens," can "pump" behavior, or "inhale" electrons at its tooth.

In 2006, graduate students at the Massachusetts Institute of Technology founded InNoVi Labs, now called Emefcient Technologies, to develop a device that uses this "breathing" process to clean wastewater. The device explored was a microbial fuel cell based on wastewater and generates electricity.

The work led to further grants from several agencies, including NASA. A Small Business Innovation Research grant from Ames Research Center's Exploration Technology Directorate built a bioelectric life-support system that would extract carbon dioxide from the air and generate oxygen, water, and methane for a crew's consumption. Ames' Intelligent Data Center funded work to monitor the wastewater while functioning as either a power-generating device or as one of the electrolytic cell that would break down waste and create hydrogen or methane.

Much of the work played into Cambrian's Emefcient technology, which is the company's trademarked name for its wastewater treatment system, the Ecolnlet Reactor, became commercially available. With a small charge applied, microbes on the anode break down waste to produce electricity, while different microbes on the cathode use that electricity to create natural gas to burn for power.

Wineries and breweries were the first facilities the company targeted, because they produce large amounts of highly concentrated wastewater. The plug-and-play system comes with extracting resources from waste—making it a "net energy producer," in the words of co-founder Jason Call. Ames' Call. Ames' Call. Ames' CEO of Cambrian.

Unit of Cambrian Innovation's Ecolnlet family of microbial electrochemical treatment system. the Ecolnlet Reactor, can be attached to treat a large volume of wastewater. Cambrian's Ecolnlet Reactor, shown here at its base on site, the Ecolnlet MINI treats wastewater. The Ecolnlet Reactor is the largest unit in the Ecolnlet family of microbial electrochemical treatment systems. MINI Membrane Bioreactor, which polishes the water for reuse.

Unlike other options, the Ecolnlet is compact and requires little oversight, in addition to producing fuel. Following treatment, facilities can prepare wastewater for reuse with the company's Ecolnlet MBR, a more traditional unit that further polishes the water, removing more than 90 percent of contaminants. Cambrian now has installations at more than 10 facilities.

Building Monitoring System Provides Insights for Sustainability

When Ames Research Center built Sustainability Base, the "greenest" building in the federal government, it counted on not only being energy efficient but also on affecting that consumption by producing sustainable energy.

That's the goal each year is to be able to show ourselves and show the public that in fact it's possible, in a building on planet Earth, using modern technology and some NASA ingenuity, to produce more energy than it can produce more than it consumes, says Ames' emphasizes Steve Zornetzer. Ames' recently retired associate director for research and development, who spearheaded the project in its formative years.

To prove that it was accomplishing that, it needed a building's wastewater system to monitor and energy was coming in and what was going out. For that, it turned to Ramon, California-based Integrated Building Solutions Inc. (IBS), which was already threatening with its expertise in energy efficiency and visualizing the energy-consuming and energy-saving activities.

With help from Ames' computer scientists, IBS was able to add an important additional feature to its dashboard software. The result is a technology we've developed for aerospace that we're now applying to commercial, says Mathew Mcewen, a NASA alumnus and cofounder of Kennedy Space Center who investigates how different light recipes affect crops.

The space station's latest plant growth system, called the Advanced Plant Habitat (APH), is more automated than its predecessors and includes a customizable LED system.

Controlling light for crop growth is also a terrestrial focus, where there is interest in indoor farming techniques enabling crops to be grown indoors. OSRAM, a German lighting company with a U.S. headquarters in Danvers, Massachusetts, has been working on such a lighting system. The Veggie LED light bar, which is a combination of LEDs, temperature control, and a software controlled panel to adjust settings.

After the Kennedy researchers were introduced to OSRAM's developers in 2017, they realized that the Veggie light bar was an excellent candidate for a commercial version of the space APH experiments. The exchange with NASA helped OSRAM refine the Veggie enough to sell Phytofy commercially, with an expected product launch around early 2019.

It's served as validation," says Steve Graves, OSRAM's commercial director for the new digital farming at OSRAM. "Let an extensive useful feedback from NIR it required to the research that went into the Veggie light recipes for NASA, and we are hopeful that their success validates this investment for many commercial applications.

The Veggie was originally specified for researching light recipes and is targeted to plant scientists in academia and in commercial growers' research and development departments.

The Phytofy system's lighting capability will be a key component in its feedstock business. It provides the lighting capabilities of the Advanced Plant Habitat, a system on the ISS that astronauts began using on the ISS in early 2018.

OSRAM's Steve Graves (right) and NASA's Matthew Mcewen install a prototype of the company's LED lighting system Phytofy in a lab in Kennedy Space Center's Orbital Processing Facility-3 bay. The effects that light color, duration, and intensity have on plants on the ISS will be studied in this facility before astronauts grow them in space. Earth, where there is growing interest in growing crops indoors in places like skyscrapers, old warehouses, or even shipping containers.

Space Station Garden Shines Light on Earth-Based Horticulture

Astronauts have been gardening on the International Space Station for years to learn how plants grow in microgravity, with the idea that space farmers can help sustain humans on deep-space missions.

One factor they experiment with is the use of different light color combinations, or "light recipes," which can have dramatic effects on plant size, shape, texture, and appearance.

"There is a light recipe that will maximize the yield of a crop, but that same recipe might not be the recipe that a light recipe we've used to grow lettuce, which—a process known as dwarfing," says Matthew Mcewen, a NASA postdoctoral research fellow at Kennedy Space Center who investigates how different light recipes affect crops.

The space station's latest plant growth system, called the Advanced Plant Habitat (APH), is more automated than its predecessors and includes a customizable LED system.

Controlling light for crop growth is also a terrestrial focus, where there is interest in indoor farming techniques enabling crops to be grown indoors. OSRAM, a German lighting company with a U.S. headquarters in Danvers, Massachusetts, has been working on such a lighting system. The Veggie was originally specified for researching light recipes and is targeted to plant scientists in academia and in commercial growers' research and development departments.

Carbon Capture Process Makes Sustainable Oil

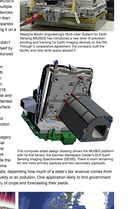

If we believe Neil Armstrong even stepped on the Moon, NASA began environmental missions with the moon space. And for just as long, the Agency has known it needed "life support" systems that minimize as much as possible the consumption of resources. Now, a spacecraft" by recycling air products, Lockheed Kessler and Space Company's R. B. Jagow and R. S. Thomas wrote in a paper from a 1966 report published by the Society of Automotive.

Over the years, NASA has developed, tested, and analyzed in that report relied on hydrogen-rich gases to react with the gaseous carbon dioxide exhaled by astronauts. The bacteria recycles carbon dioxide and water into useable by-products at a high rate, and when combined with the right type of catalyst, the gases react.

Earth is much larger than a spaceship, of course, but in ultimately all a closed-loop system is about recycling CO_2 to a growing problem.

It was with the idea of fighting climate change that Lisa Dyson and John Reed, cofounders of San Francisco Bay area-based Kiverdi, started working on the technology that powers the company. "What we did at Kiverdi was pick up where they left off," says Dyson. "Since that time, there have been so many advances in biotechnology, we asked the question: can we apply modern tools of biotechnology to this old research? We happily discovered that the answer was a resounding yes!" a lot of the NASA work.

Kiverdi relies on microorganisms to convert CO_2 , along with other simple mineral nutrients, into a wide range of materials for everyday products, such as food, clothes, personal care items, industrial goods, and fuels. Because the process uses the proteins and oils can be used in a variety of industries, she notes, from the food to the chemical industry. But you're in anything from soap to ice cream. And not only does the process use CO_2 as a feedstock, but it's also flexible enough to be more efficient during periods of abundant renewable power, soybeans for fish feed or palm trees for palm oil.

The control panel of part of a 5 cm experiment spacestrips, which would fit up to 13 times the speed of sound, required seen more robust materials and components. Kiverdi's Kessler and Space Company's Jagow and scientists responsible for creating the Kiverdi Fish Tight to increase Protective Coating for Ceramic Materials (PCCM), capable of withstanding temperatures up to 3,000.

Kiverdi's after incubating research and reports from NASA, developed a process using microorganisms to convert carbon dioxide, along with other simple mineral nutrients, into proteins. These by-products can reduce excess CO_2 in the atmosphere, while also decreasing the environmental impact of the food and chemical industries, palm oil, which is a leading cause of deforestation.

Emissive Coatings Cut Industrial Costs, Emissions, Fuel Consumption

It's no surprise that the experimental X-Plane Program has led to improvements in commercial flight, but it also produced breakthroughs in other fields entirely. For example, a high-heat coating that has helped industrial plants cut emissions and save money owes its origins to NASA.

The 9-10 and 9-30 were planned variations for commercial spacecraftare that would fly up to 15 times the speed of sound, required even more robust materials and components. Kiverdi's Kessler and Space Company's Jagow and scientists responsible for creating the Kiverdi Fish Tight to increase Protective Coating for Ceramic Materials (PCCM), capable of withstanding temperatures up to 3,000.

Researchers can extract a host of information from spectroscopic analysis of light, but the Kiverdi team relied on passing customers for images from the German DESIS instrument, which has unprecedented spectral resolution. Kiverdi's Kessler and Space Company's Jagow and Fish Tight. This corresponding model Lakeland competition shows a Kiverdi's after incubating research and reports from NASA, developed a process using microorganisms to convert carbon dioxide, along with other simple mineral nutrients, into proteins. These by-products can reduce excess CO_2 in the atmosphere, while also decreasing the environmental impact of the food and chemical industries, palm oil, which is a leading cause of deforestation.

Pointing Platform Enables Earth Imaging from Space Station

Just people think of the International Space Station (ISS) as a place to learn about space, but humanity's only outpost in space is also a unique Earth observatory.

Teledyne Brown based in Huntsville, Alabama was one of the first companies to enter into a cooperative agreement with Johnson Space Center to conduct commercial activities on the space station. The result is the Nanoracks Mantis Earth Imaging Platform, or Nanoracks MUSES, live to the ISS in 2017.

Mounted on the exterior of the space station, MUSES is a set of robotic controllers that can attach to multiple payloads. Intended mainly for Earth-imaging devices, the platform provides a more affordable option than building and launching an entire satellite. Companies can also take a device on MUSES before putting it on a satellite.

To enable precision pointing, a capability that didn't exist on the ISS, it uses a device that orients itself by the stars, as well as enhanced GPS and miniaturized inertial measurement devices.

The first customer for MUSES was the German Aerospace Center, Canadian Space Agency for Lulli and Raumfahrt (DLR), which put its DLR Earth Sensing Imaging Instrument (DESIS) on the platform. The hyperspectral imager, installed in early 2018, "sees" Earth through 235 channels in the visible and near-infrared wavelengths, providing unprecedented spectral resolution. It can sense changes in surface features as small as 30 meters across, which is intended to inform Germany's decision-making about problems like environmental and climate protection and food security.

Secondary customers, meanwhile, can buy imagery from Teledyne Brown, which retains commercial rights to the data the spectrometer gathers. The company can then sell that information to companies expressed interest in using the data to calculate the tree, type, and health of forest cover. Some users may also benefit from such data, depending how much of a stake's tax revenue comes from lumber sales. Others want to monitor water quality or air pollution. One application likely to find government and commercial applications is tallying inventory of crops and forecasting their yields.

This comp-active design drawing shows the MUSES platform on the ISS. Mounted on the exterior of the space station, the Earth Sensing Imaging Instrument (DESIS). The imager is seen with many of its nine hosted payloads and two secondary payloads.

Algorithms to Detect Clouds Forecast Global Crop Production

I started as an algorithm to detect clouds in satellite imagery, but now it's helping to forecast the global production of key security in the strategic world by guiding futures trading on Wall Street.

Earth-imaging satellites monitor forest and crop health, canvas and glacier coverage, and a host of other environmental activities. Pixels capturing clouds and their shadows throw off the data, so NASA has long had a need for algorithms that detected cloud patterns and removed them.

In 2002, in preparation for the Landsat 8 satellite, engineered at Goddard Space Flight put out a Small Business Innovation Research (SBIR) solicitation for software capable of detecting cloud cover, which a contractor called Analytical Graphics Inc. (AGI) developed a company to win. Today, Exelis Visual Information Solutions (VIS) of Boulder, Colorado, is the SBIR contractor with Sterna in 2004 and 2005 focused on analyzing satellite images to identify surface features such as water, vegetation, and snow. Algorithms forest fires, and more. GDA also used the funding to automate its systems, which regularly pull, correct, and analyze raw data from several Earth-imaging instruments, and to build a 30-year archive of petabytes of historical and current satellite images across agricultural monitoring entities.

Calculations of crop condition, growth, and growth, and especially forecasts of crop productivity, interest organizations like the U.S. Department of Agriculture's Foreign Agricultural Service, which provides commodity estimates and predictions to guide marketing edge for U.S. producers. The agricultural service became GDA's biggest customer, but others, such as agricultural commodity companies, commodity traders, and food futures companies, also became clients.

The Foreign Agricultural Service uses GDA's tools, among other sources, to create its monthly estimates for all major crops and crop futures markets move according to those estimates. They also help the service predict shortages in food and agriculture.

Automated software at the GDA Corporation worked with NASA Sentinel-2A images from various satellites, combined cloud-free images of over 50 countries, and then used algorithms to analyze the data. The information can be gathered from the data, including total global crop yield.

This map shows the correlations between GDA Corporation's crop yield estimates and USDA data. The correlations were calculated for corn, soybean, and wheat (2006 and 2017) in the American Midwest, with deeper shades of green indicating stronger correlations. Combining satellite data with more complete historical data generate more consistent and dependable forecasts.

Infrared satellite imagery captures the shapes of an active growing cycle for crops in the American Midwest. Algorithms developed by GDA Corporation help identify farmers crop coverage. Image here shows that one crop (red) is growing more vigorously than another (green), while a third (blue) has been harvested, and the fields stored dry soil thereafter.

"This definitely fits in with the goal of taking NASA science and capabilities and applying those to areas of public need," says Tom Stanley of Sterna.

Information technology

Software and information technology are already woven deeply into NASA's fabric of daily life. Engineers use computer features to more quickly design new, and test current, aircraft and spacecraft systems. Astronauts in space fix problems and perform repairs on stations. And soon the web will experience the same change through computer systems and software advancements that will enable astronauts to explore farther into space than they have, and they got their start at NASA.

Space Mission Planning System Targets Advertising with Precision

Most people don't realize that every time they see an online ad, it was placed there after a near-instant auction for that spot. The entire bidding and selling process is automated and takes about a tenth of a second.

One of the leading companies now driving that process uses algorithms based on an approach its founders helped invent for planning NASA missions.

Around 2004, NASA Headquarters paid several contractors to study possible architectures for an astronaut mission to the moon or Mars. The study also included a team of faculty and graduate students at the Massachusetts Institute of Technology (MIT). The MIT team started with an entirely different method for the task, looking at all options without any underlying assumptions about the mission.

The team created the Object Process Network, a meta-language based on about 35 major decisions needed for any one mission to a planetary body. They ended up with 1,152 possible mission architectures, which could be evaluated and sorted for weight, cost, and other factors.

Two of the team members then founded Boston-based dataxu and identified digital advertising—a fast-paying field that still had glaring inefficiencies and lots of room for improvement—as a great market for the software they'd helped develop.

When new bidding data arrives, the modern format for online ad sales, was born in 2009, dataxu was one of the companies that made it possible.

The company's algorithms consider all options for a given ad slot and immediately narrow down to about 20 candidates, based on factors like size and content. The platform then uses a more advanced formula to determine the probability of the user responding to each ad and selects one.

The company says its service is 35 to 40 percent more efficient than its competitors in terms of cost per click-through. Recently, dataxu broke into television advertising, where it says it finds three times the audience competitors do for the same price.

The software that dataxu now uses to place advertisements was originally created to select architectures for missions to the moon and Mars, making decisions on whether a habitat will sit in the lander provided or needs to include an escape stage and dock with a capsule left in orbit after leaving the surface.

The online ad bidding service dataxu offers is 35 to 40 percent more efficient in terms of cost per action, than its competitors, which have 200 users.

Tiny Star Trackers Help Spacecraft Find Their Place

NASA tackles some of the universe's biggest questions, and the tools it needs are often big, in size and cost. But Corvinus, a Maryland-based Adcole Maryland Aerospace, with Small Business Innovation Research (SBIR) funding, has designed a modern take on an ancient navigation device that is tiny, cheap, and potentially revolutionary.

The device, a "space sextant," fits inside a CubeSat but can track stars with the accuracy of much larger instruments.

Star trackers are important not just for navigation but because "the better we can point our satellites, the better images and science data we can get," explains Alice Liu, attitude control engineer at Goddard Space Flight Center, which funded the SBIR work. "We need to be able to point at a direction where we want to take a picture and have to be stable while we take it."

Where before, NASA might have spent tens or even hundreds of millions of dollars for a sun-observing satellite to get the kind of resolution it needs, with less expensive CubeSats and accurate star trackers, it is far more feasible for researchers to, for example, deploy multiple units to observe from different angles.

"The number of measurements can go up. And, if something fails, the mission isn't lost completely," explains Jason Mitchell, assistant chief for technology, Goddard's Applied Engineering and Systems Analysis division.

"It really does revolutionize the way that we can think about generating measurements. It enables many new possibilities for science."

The company now aims to scale sextants in a variety of configurations and as stand-alone devices, primarily for Earth-observation satellites.

Small satellites, often called CubeSats, are far less expensive to build and launch than traditional satellites, but to use them for scientific research, engineers have had to develop new tools that are small and inexpensive but still precise and powerful enough to get good results.

This tiny device fits inside a CubeSat and contains all the hardware and software needed to track stars with the accuracy of much larger, and costlier, units. Developed by Adcole Maryland Aerospace with funding from several SBIR contracts, it is at least an order of magnitude more precise than previous pointing devices for CubeSats.

Software Toolkit Steadies Rockets

"Combustion instability is the part of rocket science that makes rocket science hard," Paul Giver—and he's not joking. The phenomenon, in which oscillations or vibrations build up, can cause an engine to explode.

"It's probably one of the highest risks that we encounter when we develop an engine," Matt Casiano, an aerospace engineer at Marshall Space Flight Center.

Giver's company, Tullahoma, Tennessee–based Giver Taylor Consulting, Inc., has developed a tool—the company refers to it as the Universal Combustion Device Stability (UCDS) process and toolkit—to try to lower that risk. Based on a computer code to solve the problem of combustion instability into different layers, it can predict how an engine will behave and why, enabling engineers at NASA and beyond to change problematic factors during the early design phase.

Casiano was part of a team that worked with GTL to test one component of that toolkit. Overall, Casiano said, he wasn't a full checkout of their tool but a demonstration of its capability and how it can provide information to design engineers."

Giver says the UCDS software has the potential to cut rocket costs by a huge margin, because it can simplify the design process so significantly. "Combustion instability, depending on how you look at it, accounts for about half the money the United States has spent on rockets, in terms of cost overruns, hardware damage, testing, and program cancellation," he says.

In 2014, GTL released its Resonance software as a stand-alone program, and it has sold a few licenses to commercial aerospace firms as well as government labs. The company also plans a spring 2019 release of the full UCDS software toolkit, in the fourth generation, now that it's had more time to develop and validate it.

The market is small, Giver says, but he sees a fair amount of growth potential, not just in rocket design but for jet engines and even power plants.

NASA test fires one of the Space Launch System's boosters, which could help power astronauts to the moon. Software developed with SBIR funding for a new rocket, one of the biggest risks is combustion instability from the engine, when the vibrations resonate and amplify until it explodes. Software from Giver Taylor Consulting, Inc., can predict those dangerous stages of instability, but it would be far easier and less costly to fix any problems earlier in the design phase.

Giver-Taylor Laboratories (GTL) has created a software toolkit that predicts and analyzes structures for combustion instability, calculating the bulk flow of energy and then continuing on in layers, analyzing acoustics, vortices, and flame. The company used SBIR funding to develop the Hadgraph 2SPI contractor from NASA to help design test fire loaded, including the acoustics component called Resonance, which generated the image here.

Shadowcia stories are famously the best, but what differentiates them from other 3-D graphics software is the ability to create and analyze acoustics—back to the difference in materials and shape. Although GTL's toolkit was originally designed for rockets, the physics of musical instruments are similar, and GTL has used its software to analyze the signatures of just what makes for beautiful sounds.

Low-Cost Transceiver Will Allow First Laser Mass Communication

Since the advent of the laser in the 1960s, engineers have struggled to use light beams in free space to send information the way we use radio waves. No one could have expected a solution to come from a former aviation data executive like Mark LaPenna—least of all him.

LaPenna left a comfortable job in 2014 to start an aircraft tracking company. Then he encountered a problem. The way it would have required satellites to gather far more information than they could possibly beam down to Earth via radio, because the radio spectrum has limited capacity and is becoming overcrowded. He was about to dissolve the company when a friend at NASA suggested he consider a technology the Jet Propulsion Laboratory had patented for license.

A team there had come up with a simple, low-cost laser communications transceiver that could avoid the constraints of radio communications. While radio waves are from 10 to 50 kilometers long, light wavelengths are measured in microns. This more concentrated beam gives it much greater capacity to carry information.

Upon learning of the transceiver, LaPenna scrapped his original plans, realizing that laser communications could meet a larger need. He licensed the technology.

In an effort to enable laser communications from space, a team at the Jet Propulsion Laboratory put together this low-cost laser transceiver from commercially available, off-the-shelf parts. Xenesis licensed that technology and is building a business around it.

Obstacles like weather interference, a lack of ground stations, and the need for an entire constellation of satellites have scuttled other attempts at large-scale satellite laser communications. So, while LaPenna's Alberta-based company has the technology to encourage and gain access to a future network of ground transceivers, it will start by offering unhackable laser communication over land.

This will let banks, hospitals, and other entities that transmit large amounts of sensitive data to do so more securely than is currently possible.

For the long term, the company is partnering with businesses that are jointly developing networks of laser-communication ground receivers and space capabilities. Xenesis plans to launch the first two of those pods in its constellation in 2020, to be followed by hundreds more. All of this will one day enable ultra-secure, high-speed satellite Internet access.

In the future, Xenesis plans to use laser communications to offer large-scale, high-speed, and unhackable Internet access. Here, a ship in the ocean, the company will start with over-land tests, but it's also providing unhackable connections, for example for hospitals and banks, which transmit large amounts of sensitive information between their various locations.

NASA Code Speeds Nation's Aircraft, Spacecraft Design

Following the Challenger disaster of 1986, NASA wanted to explore the possibility of dropping the Space Shuttle's solid rocket boosters before they burned out in case of a malfunction. To better model the aerodynamics of multiple bodies in flight, Parker Lessard, one of the members of a team at Ames Research Center proposed using an improvement to computational fluid dynamics (CFD) software that is now used for aircraft and spacecraft designers in the United States' the oversee of gulf method.

All CFD software breaks down complex geometries into grids of simple shapes, including breaking the air around the vehicle down into tiny cubes. CFD then generated these grids around each major component and calculated the airflow. Instead, overset grids overlap and interact with each other, as real air flows would, yielding more realistic simulations.

In the early 1980s, NASA's models for computational fluid dynamics (CFD) modeling of the Space Shuttle consisted of three grids, 10,000 surface points, and 100,000 volume points (left). By the 1990s, improvements created the overset grid method of CFD, creating and running the OVERFLOW CFD solver and accompanying software throughout the 1990s and '00s, which could model complex configurations (center). By 2010, the Space Launch System included 267 overlapping grids with 696,000 surface points and 34.8 million volume points (far right).

NASA developed a suite of software that enables overset grids and is now widely used: The Chimera Grid Tools program generates the grids. Pegasus preprocessing software integrates them with each other and with all the surfaces being modeled, and colleagues created the OVERFLOW solver that actually runs the simulations.

Today, NASA's OVERFLOW CFD solver and accompanying software are used to accurately model the detailed interactions of flows around multiple bodies in flight. Available to the public, they're used by virtually every aerospace company in the United States, many foreign companies, dozens of federal agencies, and more than 85 universities.

Tiny Springs Improve Electronic Reliability

Space exploration comes with many giant challenges, but some are downright tiny. One project to solve a connection issue in printed circuit boards has resulted in a miniature solution—a micro-coil spring less than half a millimeter in diameter—that could have an outsized impact on electronics.

Printed circuit boards are layered with copper lines and pads that connect electronic components together. Typically, the components are soldered to the board, which provides a strong adhesion and allows electricity to pass through. However, those joints can break when things heat up.

"We wanted something that might be a little more robust from a handling perspective, with higher reliability from a thermal perspective," says Mark Strickland, an engineer at Marshall Space Flight Center. He and fellow Marshall engineer Jim Nesbet developed a micro-coil spring connector that lasted up five times longer and could withstand vibrations at forces of up to 10 Gs.

The biggest challenge, the two explain, is how to connect the spring securely to the leads. "If you look at a spring from the side, you have a nice flat sticks out the bottom that is not flat," which makes it difficult to attach perpendicularly to the board, Strickland says.

The springs like this one-hair-connect electronic components to circuit boards. Because they are flexible, they make stronger, longer-lasting connections, which is great for space—and high-demand applications on the ground.

The pair worked out a system, and in 2014, their innovation won the top prize in the electronics category of Tech Briefs' Design the Future challenge. Since then, Nesbet and Strickland have been working to bring the technology to market. However, company CEO Martin Hart emphasizes that the process first had to be streamlined and scaled up for mass production.

"NASA does a great job at figuring out a better way to do things, but it's not a blueprint," Hart says, noting that to attach even a single component would typically take an array of some 1,000 to 2,000 springs.

Applications include anywhere with large temperature swings, from downhole drilling to car components stotted into the engine compartment, or even a desktop computer with large ceramic parts. Hart also sees potential in the medical devices, like hearing aids, and adds, "We're still at the beginning of discovering the market."

Collaborative Platform Trains Students in Simulation and Modeling

It's the 2050s. On the far side of the Moon, in the vast, pockmarked South Pole-Aitken Basin impact crater, groups of college students from around the world are building an outpost.

Of course, this wouldn't be possible without NASA technology.

Moon City exists in a simulation in which through the Distributed Observer Network (DON), a simulation viewer created at Kennedy Space Center, the students are all in fact at their respective universities, in the present day, collaborating to build the virtual lunar city as part of the Simulation Exploration Experience (SEE). It is a program that introduces them to collaborative modeling and simulation, a subject rarely taught in school. Sixty to 80 students participate each year.

NASA created DON to allow engineers to run simulations created in various formats and from many platforms, making it easier for them to be preserved and shared. A game engine—currently Unity 3—enables the simulation visualization.

Employees from Kennedy and Johnson Space Center came up with SEE after realizing that, while modeling and simulation are widely used across many industries, few people applying for those jobs know much about it. Armed no universities offer modeling and simulation degrees.

NASA uses a variety of tools to create simulations, including the Distributed Observer Network (DON), a viewer that can render the aerodynamics of a Space Shuttle descent here. The Distributed Observer Network (DON) can read and display any of those simulations.

In addition to DON, NASA supplies the teams with High-Level Architecture-based software that ensures the accurate trajectories and positioning of the planetary bodies. And the detailed model of the lunar Aitken Basin site provides the challenge's virtual setting was created at NASA's Jet Propulsion Laboratory.

SEE's overarching goal is to enhance students' employability, but faculty at participating schools can tailor activities to fit their own programs and curricula. The results are already proving out: not only are participants finding jobs, but four people who participated in the program as students are now teaching simulation in colleges and complete in SEE as faculty.

Meanwhile, other organizations are building their own software similar to DON—possibly following NASA's example. DON was the first such program to use a game engine, a practice that is now common.

A novel passes in front of part of Moon City, the simulated lunar outpost constructed by teams of students from around the world in the Simulation Exploration Experience.

Industrial Productivity

Continually identifying, developing and applying cutting-edge technologies that help customers in many industries in every phase of manufacturing, from product design to delivery and support. Also, helping customers use these technologies to advance 3D printing, and make Earth more hydrocarbon, more efficiently.

Spray Analyzer Turns Up in Cars, Planes, Medicine, Cutting-Edge TVs

At first, NASA just wanted a way to analyze fuel sprays in a turbine's environment such as a jet engine. What William Bachalo created to do just this need in 1984 has since been used for applications in a wide range of industries: printers, medicine, agriculture, and now the latest cutting-edge development in smartphone and television screens.

After founding Aerometrics Inc., Bachalo and his partner developed the Phase Doppler Particle Analyzer (PDPA) under Small Business Innovation Research contracts with Lewis Research Center, now Glenn Research Center, to measure and characterize the interaction of atomized fuel sprays in terms of droplet sizes, velocity distribution, turbulence intensity, and fluctuations. It remains the standard for spray characterization to this day, and comes with work on using lasers to characterize soot emissions, also funded by NASA, as the basis for the products offered by his current company, Atlanta, California-based Dantec Technologies Inc.

The PDPA technology has been used to test and validate advanced materials for fuel-efficient combustors and to design or monitor spray systems in agricultural pesticides and fire sprinklers. An adapted version can characterize sprays of medicines, aerosols, and mists.

In 1995, Aerometrics merged with a competitor, and in 1998, Bachalo cofounded Artium, starting to produce the technology for Most automobile manufacturers use Artium PDPA instruments to optimize the efficiency of fuel fuel injectors, among other applications. Others use them in spray-coating pharmaceuticals, developing and testing inhaler printers, and certifying aircraft parts.

PDPA testing technology has also found a surprise—market in the organic LED, or OLED, display business. These new screens, with their deep blacks and rich colors, are used in smartphones and televisions. Initially, the pixels were made through a lithographic process, but manufacturers are now working to print the screens with inkjet technology, with Artium devices providing quality control. Printed screens should significantly lower the prices of OLED displays. Meanwhile, Artium's revenues have doubled in the last year.

Artium's Phase Doppler Interferometer is used to test fuel injectors at a customer's facility. The device uses lasers to measure droplet velocity in the sprayed organic soot to fuel nozzle and at engines.

Cognex LED or OLED displays are known for their rich colors and deep blacks, as well as for being thin and often flexible. But they're also difficult to make. Even a tiny flaw can ruin a display, and the defects can be the screens' organic dots into inkjet printers, a process that uses Artium's spray characterization technology for quality control.

Deep-Space Food Science Research Improves 3D-Printing Capabilities

Cone health is critical to any organization dedicated to maintaining astronaut nutrition gets harder the farther they get from Earth and any chance of a resupply mission. A crewed mission to Mars, for example, will have to pack food for up to three years in space.

In its search for new ways to provide nutrients and variety to astronauts, NASA in 2013 established the Small Business Innovation Research (SBIR) contract to a company with no novel idea. Systems and Materials Research Corporation (SMRC) was building a system to create accurate pictures and textures—the ribbon on the edge of a cake, a flower—in seasonally themed cookies, for example.

Beerkes is trying a variety of business models. One route is a stand-alone machine that bakers can use to design custom confections. "We will have one in a popular bakery in Omaha, Nebraska, by December," Noy customer can go, select a shape, print their cookie, and right there get a fresh, customized cookie on the spot."

Beerkes has other 3D-printed food technology in the pipeline as well. For example, Contractor is working on a recovery bar machine that can personalize a bar based on a latex lunch nutrition bar depending on a person's individual needs, such as genetics, metabolism, and blood markers.

NASA astronauts Chris Ferguson (left) and Doug Hurley participate in a food-tasting session during a simulated mission to Mars in August 2013 at Johnson Space Center. As NASA looks to long-duration human missions to the moon, Mars, and beyond, it's researching how to preserve food for up to five years in space. The agency is also looking for ways to benefit from and enjoy the food they eat while they are far from home.

One of Beerkes' founder Angel Contractor's first forays into 3D printing food began with customized pizzas built from dough, sauce, cheese, and toppings such as pepperoni. Systems and Materials Research Corporation's printing tasty foods that combined nutrients, oil, and other liquids for the knowledge and technology that made his 3D-printed pizzas possible.

One application for Beerkes's technology, developed in partnership with NASA, is to create personalized nutrition bars for astronauts. Certain breakfast or lunch bars tailored for a person's needs. Image courtesy of SMRC

Simulated Space Dirt Supports Future Asteroid Mining

When companies begin mining asteroids, they probably won't be seeking precious metals. Some space rocks contain such materials, but the cost of transportation is far more valuable: water.

Water is not only necessary for life, but it contains that other necessity, oxygen, which along with water's other ingredient, hydrogen, can be turned into NASA's favored rocket fuel liquid hydrogen oxidized with liquid oxygen.

But building the tools to harvest these materials from an asteroid will first require tests on Earth. That's why Deep Space Industries Inc. of Bishop, California, has developed a new simulant, one of a few businesses looking toward space mining, kept at NASA's 2015 Small Business Innovation Research solicitation to develop soil and crust simulants that the surface composition of four types of asteroids.

For NASA's Jet Propulsion Asteroid Redirect Mission, researchers wanted to test new methods of anchoring and excavating regolith, the rocky material on asteroids that makes up the surface. Engineers can't determine how to operate anchoring and excavating equipment in relative anchoring and excavating equipment becomes tricky. The Space Agency wanted simulators of the surfaces of four types of carbonaceous chondrite, a class of asteroids containing absorbed carbon, water, and organic compounds, all useful for space travel.

DSI delivered a total of more than 1,000 pounds of asteroid simulants to Kennedy Space Center in January 2016.

Several universities have also purchased the materials, as have other space agencies and companies interested in space mining.

Because it's so expensive to put water or anything else into space—about $10,000 per pound—DSI imagines extracting a couple thousand tons of water from an asteroid and using half of it as fuel to carry the rest back to Earth orbit. There, it would be available for use by the fuel depots planned by the company.

The water could also be used for fuel by filling a satellite from low-Earth orbit (LEO) and then to eventually use elements harvested from asteroids to manufacture parts in space, further saving on launch costs.

Researchers know a lot about asteroids from analyzing the ones that have fallen to Earth. The Murchison asteroid, a piece of which is shown here, struck near Lake Murchison in Australia in 1969. This is a CM-type asteroid, a carbonaceous chondrite that's rich in water and other carbon compounds. CM type asteroids present a potential source of water for space travelers, and their surface structure and are one of four types Deep Space Industries (DSI) simulates.

DSI cofounder Ian Issy has admired simulant properties in smelts of a range of grain sizes.

DSI ultimately wants to set up asteroid mining operations with spacecraft that can operate autonomously. The company's Prospector-1 spacecraft, its first needs to be tested in asteroid simulant to see how it will perform.

Vibration Isolator Steadies Optics for Telescopes

Anybody who has ever tried to hold a camera steady for a long exposure knows that the slightest movement of the camera shakes, and the image blurs. The same can happen with images from telescopes and any kind of long-range image. In fact, for some very sensitive optics, even ordinary ground vibrations can be enough to throw off the results.

That's why, explains Barry Goodwin, instrument system engineer at the Massachusetts Institute of Tech., "When we need a hot cabinet a vibration isolator to work in a few different ways, but essentially they create a mount between the optics and external vibrations won't interfere with sensitive measurements.

NASA has sought several vibration isolators from Los Angeles-based Aerospace Corp. over the years—including a system for the James Webb Space Telescope of six isolators, specially built to hold up to 10,000 pounds each. That's a larger capacity than any of the other isolators that the company believes, the largest-capacity vibration isolator anywhere for this type of application.

JPL also recently turned to Minus K to build it an isolator for testing space-borne optics, which requires a fairly high degree of vacuum compared to typical industry standards for innovation. "There are different requirements for space," he says, "and we're the only coating that we study, and we do. We learned about what special requirements were needed at high vacuum levels."

Today, the company has taken this experience and translated it into new vibration isolation clients that make semiconductors and optics. "When building chips and measuring chips, they need to have as close to no vibration as possible," he notes. Other customers include the Department of Defense and the National Laboratories.

Scientists hope to use the James Webb Space Telescope to peer deeper into the universe than ever before. To ensure the instruments get crisp, clear images, they'll be fitted with vibration isolators, including this one, some of which required a "vibration isolator" to hold it and keep it steady.

For a project with the Jet Propulsion Laboratory, Minus K Technology built a vibration isolation system for testing optics in a vacuum. The company works with similar models for other customers, including to our quality control department.

IonCCD Enables Fast, Reliable, Inexpensive Mass Spectrometry

NASA's Jet Propulsion Laboratory (JPL) has a long history of pioneering the use of the charge-coupled device, or CCD, which it used to build some of the world's first digital cameras. In the mid-1990s, JPL began to look after taking the first digital astronomical photo. JPL engineers started to look for ways to replace traditional film with CCDs in other instruments, including mass spectrometers.

Mass spectrometers identify the ratios of various isotopes in a sample, which can reveal information about its age, how it was formed, and more. The size of mass spectrometer one JPL engineer wanted to use for space missions was about the size of a refrigerator, with components for separating various isotopes according to where they hit a focal plane, traditionally made with photographic film. He and a colleague devised a version with a CCD array as its focal plane, which was much easier to use and far more energy efficient.

But they didn't have the funding to build it. Instead, they helped a startup company license the intellectual property and build the device.

In the mid-2000s, the company had sold several mass spectrometers based on the CCD focal plane, which they called the IonCCD. Then Dr Analytical, based in College Station, Texas, purchased the company and started offering IonCCD as a standalone product. The company also packaged it with a camera controller and power supply to create the first series of the IDS 2030 Charged Particle Detector.

Mattauch-Herzog devices deliver accurate results much more quickly than other mass spectrometers by counting all isotopes simultaneously. The IDS 2030 was born to be smaller, cheaper, more rugged, and far more energy-efficient.

Customers include analytical chemists, the pharmaceutical industry, and the military's threat detection applications. The IDS 2030 also has customers in spatially resolving ion-mobility spectrometry, often used for drug and explosive detection.

Images on the faint Earth and Opportunity rovers, including the Panoramic that took this self-portrait, had to meet rigorous requirements, obliging JPL engineers to develop new technologies. Among them were charge-coupled devices, or CCD, which JPL helped develop in the 1970s. These highly photosensitive, low-power, low-noise, high-speed yet inexpensive devices are now ubiquitous in digital cameras. Engineers are now designing a mass spectrometer with a CCD array for a focal plane, although they require more modifications.

In the Mattauch-Herzog mass spectrometer configuration, ions are accelerated by an electric field, then bent by a magnetic field. The ions are then by using to separate them by where they hit a focal plane that detects and forms images of the ions. Mattauch-Herzog devices can be miniaturized this within a small, rugged, inexpensive, energy-efficient device.

DI Analytical's IDS 2030 Charged Particle Detector is based directly on the technology licensed from JPL for a CCD-based mass spectrometer. The small, affordable, robust, and efficient device offers quick, accurate results for applications including drug and explosive detection and pharmaceutical industry, military threat detection, and more.

Beryllium Blazes New Trail for Telescopes

The James Webb Space Telescope is a mechanical eye so penetrating it will look back in time to the dawn of the universe. And its cornea of lightweight, durable mirrors is largely to thank for its ability to see so far.

For the mirrors, NASA needed a material that would maintain a stable shape at temperatures approaching absolute zero and that could withstand the hazardous journey into space. The agency settled on beryllium, which stays shrinking at about -330 °F and is stiffer than other options, allowing for lighter mirrors.

When NASA was planning the telescope, Lafayette Hughes, Ohio-based Brush Wellman, now known as Materion Corporation, was one of the world's big beryllium producers, and Goddard Space Flight Center turned to the company to provide the raw blanks that would become Webb's mirrors.

Beryllium comes in other shapes and sizes, both—to create an "exotic alloy" and to make smaller containers for lunches and lifelines. Primefields embeds the pieces in a matrix of food-grade polyester to coat the container, and the food—or beer—inside "will stay colder for about two to four hours longer," Bilez says, depending on the container's material.

A radiographer at Brush Wellman, now Materion Corporation, prepares beryllium powder to be made into a mirror for the James Webb Space Telescope. The machined mirror is create a mirror for the James Webb Space Telescope.

The James Webb Space Telescope mirrors are removed from Marshall Space Flight Center's X-ray and Cryogenic Facility in preparation for the mirrors are made of beryllium to get because the material will deform predictably when taken from room temperature to near absolute zero.

And as some NASA satellites. Back on land, beryllium is used in most X-ray and mammogram machines, among other applications.

Phase-Change Coating Absorbs Heat from Rockets, Pipes, Beer

Most people enjoy an icy drink without thinking about the physics of the phase-change reaction inside the glass. But Primefields Inc. has made a business out of the process heat and energy. It's something NASA has harnessed for more extreme environments, and now as NASA-invented phase-change coating could keep the chill in passenger planes—or be the key to an ice-free cooler.

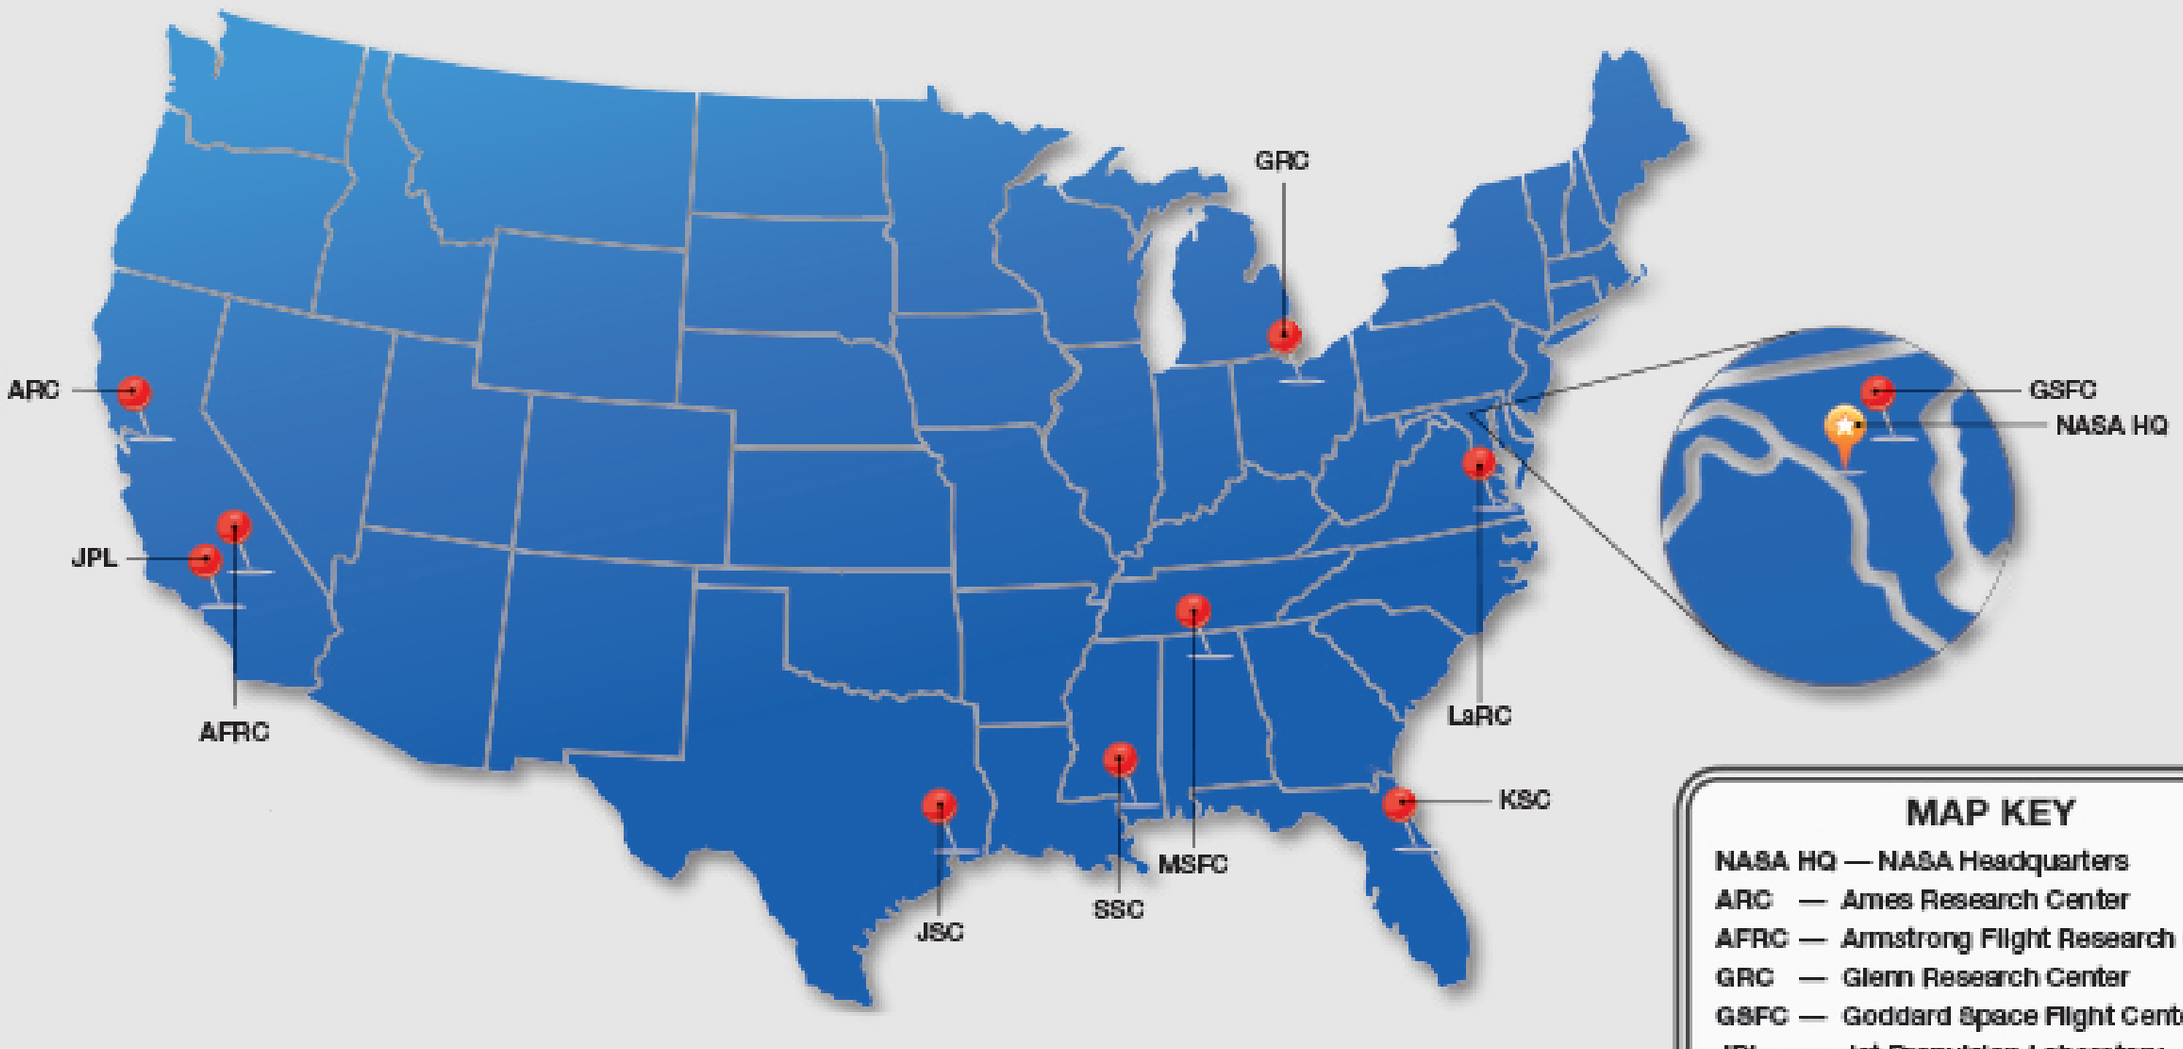

In the early 2000s, Marshall Space Flight Center materials scientist Raj Kaul developed a phase-change coating made of a paste that could be applied to parts aiming to better protect the Space Shuttle's solid rocket boosters. Previously, NASA had used a material called MCC-1 (for Marshall Convergent Coating), which was "basically a mixture of cork and epoxy," Kaul says. "The cork will burn, and that burning process also removes the heat. Plus, it ablates—the layer of cork burns off, and the heat energy is expulsed, and then you have to reapply it."

Because the coating was designed to burn off, however, there remained a danger that the process would cause damage. Kaul's new phase-change coating was more reliable, he says, and effective with a much thinner layer. "Another advantage," he adds, is that it "could be reused."

A commercial license was quickly snapped up by entrepreneur Chris Bilez, who founded Primefields to market the coating. For airplanes, Bilez explains, the idea would be to coat the back end of the plane, to prevent heat damage from the jet engines. He has also seen interest from a company that makes heat traps for Veterans Affairs hospitals.

The Shuttle solid rocket boosters were protected from the incredible heat generated at launch by a coating designed to burn off. In the early 2000s, Marshall Space Flight Center's Raj Kaul developed a new coating, suspending phase-change materials in a paint-like plastic that could absorb the heat without burning off, offering more reliable protection.

After licensing the patent for the phase-change coating from Marshall, entrepreneur Chris Bilez founded a company, Primefields, and is working on a number of products, including an ice-free cooler.

Bringing NASA Technology Down to Earth

NASA's Technology Transfer Program pursues the widest possible applications of Agency technology to benefit U.S. citizens. Through partnerships and licensing agreements with industry, the program ensures that NASA's investments in pioneering research find secondary uses that strengthen the economy, create jobs, and improve quality of life.

To learn more about licensing NASA technology, visit http://technology.nasa.gov. General inquiries may be directed to the Spinoff Program Office at spinoff@nasa.gov. To suggest a story about a commercial product or service developed with NASA technology, assistance, or know-how, contact *Spinoff* at the email address above, or visit http://spinoff.nasa.gov.

NASA Headquarters provides leadership, policy, strategy, resource allocation, and media relations for technology transfer activities agencywide.

Technology Transfer Program Offices at each of NASA's 10 field centers represent NASA's technology sources and manage center participation in technology transfer activities.
